Abstract: We introduce and study a deformation of the geodesic curvature for a given spherical curve γ . Also, we define a new type of evolute and two Fermi-Walker type derivatives for γ . Some concrete examples are detailed with a special attention towards space curves with a constant torsion.

Key words: Spherical curve, flow-geodesic curvature, flow-evolute

1. Introduction

The subject of curves on a given Euclidean surface $S \subset \mathbb{R}^3$ is a classical one but still preserves the flavor of a charming framework. Even more so if the given surface is a remarkable one, e.g. the unit sphere; recently, the curve shortening flow was studied on S^2 in [6]. The purpose of this work is to contribute to this setting with a deformation of the well-known geodesic curvature, somehow in the spirit of [9].

Recall that the geodesic curvature k_g of a curve $\gamma \subset S \subset \mathbb{R}^3$ is provided by an orthonormal frame $\mathcal{F}(\gamma, S)$ adapted to both γ and S ; for S^2 we denote by \mathcal{F}_s with s from "spherical". Our idea is to rotate this frame in the normal-radial bundle $\gamma^\perp := \{(x, v) \in (Im \gamma) \times S^2; v \perp x = \gamma(t) \in \mathbb{R}^3, t \in I\}$ (the notations are explained below) by an angle equal exactly to the parameter t of γ . Then we call this new one flow-frame and since we use an orthogonal transformation, i.e. a matrix from $SO(3)$, this frame yields a new curvature called flow-geodesic curvature; for the case of plane curves, this notion is already studied in [4]. In turn, this new function gives a new evolute for the given curve. As new tools in studying spherical curves we introduce a spherical, as well as a flow-spherical Fermi-Walker derivative, and both these derivatives are computed for our main vector fields along γ .

The contents of the paper is as follows. The first section is a short survey on spherical curves and we point out the relationship between k_g and the pair (curvature, torsion) of the given spherical curve γ considered a space curve. The second section gives the new curvature and the new evolute; a main result establishes the computational expression of the new curvature. The third section is concerned with several examples and some related remarks; a special attention is devoted to find flow-flat curves, i.e. spherical curves having a vanishing flow-geodesic curvature. Our study is connected through two examples with the subject of space curves having a constant torsion, a theme of great interest in contemporary differential geometry of curves.

2. Preliminaries: spherical curves

The setting of this section is provided by the space \mathbb{R}^3 which is an Euclidean vector space with respect to the canonical inner product:

$$\langle u, v \rangle = u^1 v^1 + u^2 v^2 + u^3 v^3, u = (u^1, u^2, u^3), v = (v^1, v^2, v^3) \in \mathbb{R}^3, 0 \leq \|u\|^2 = \langle u, u \rangle. \quad (2.1)$$

Let $S^2 = SO(3)/SO(2) = SO(4)/U(2)$ be the unit sphere of $\mathbb{E}^3 := (\mathbb{R}^3, \langle \cdot, \cdot \rangle)$ and fix a smooth regular space curve which is a spherical one, $\gamma : I \subseteq \mathbb{R} \rightarrow S^2 \subset \mathbb{R}^3$. Its spherical Frenet frame is:

$$\mathcal{F}_s := \begin{pmatrix} \gamma \\ \mathbf{t} \\ \mathbf{n} \end{pmatrix}, \quad \mathbf{t}(t) := \frac{\gamma'(t)}{\|\gamma'(t)\|}, \quad \mathbf{n}(t) := \gamma(t) \times \mathbf{t}(t), \quad (2.2)$$

and the corresponding spherical Frenet equation is provided by [11, p. 338]:

$$\frac{d}{dt} \mathcal{F}_s(t) = \|\gamma'(t)\| \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & k_g(t) \\ 0 & -k_g(t) & 0 \end{pmatrix} \mathcal{F}_s(t). \quad (2.3)$$

The smooth real function $k_g : I \rightarrow \mathbb{R}$ is called the geodesic curvature of γ and its computational formula is:

$$k_g(t) := \frac{\langle \mathbf{t}'(t), \mathbf{n}(t) \rangle}{\|\gamma'(t)\|} = \frac{\det(\gamma(t), \gamma'(t), \gamma''(t))}{\|\gamma'(t)\|^3}. \quad (2.4)$$

Moreover, the usual curvature k of γ as a space curve is $k = \sqrt{k_g^2 + 1} \geq 1$ and the torsion of γ is $\tau = \frac{k'_g}{k_g^2 + 1}$. Recall also that γ is convex if $k_g > 0$ and if $k_g = 0$, we say that γ is a spherical-flat curve. Sometimes, another adapted frame is used, namely the Darboux-Ribaucour frame, which is connected to \mathcal{F}_s through a cubic root of the unit matrix I_3 :

$$\begin{pmatrix} \mathbf{t} \\ \mathbf{n} \\ \gamma \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix} \mathcal{F}_s(t), \quad R = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix} \in SO(3), \quad R^3 = I_3.$$

The rotation matrix R is denoted by \hat{q} at page 276 of [1]. The evolute of γ is a new spherical curve:

$$Ev(\gamma)(t) := \frac{k_g(t)}{k(t)} \gamma(t) + \frac{1}{k(t)} \mathbf{n}(t) \in S^2. \quad (2.5)$$

An important tool in dynamics along curves is the Fermi-Walker derivative. Let \mathcal{X}_γ be the set of vector fields along the curve γ . Then the Fermi-Walker derivative is the map ([5]) $\nabla_C^{FW} : \mathcal{X}_\gamma \rightarrow \mathcal{X}_\gamma$:

$$\nabla_\gamma^{FW}(X) := \frac{d}{dt} X + \|\gamma'(\cdot)\| k [\langle X, N \rangle \mathbf{t} - \langle X, \mathbf{t} \rangle N] \quad (2.6)$$

for (\mathbf{t}, N, B) the usual Frenet frame of γ . Inspired by this expression, we introduce a spherical Fermi-Walker derivative:

$$\nabla_\gamma^s(X) := \frac{d}{dt} X + \|\gamma'(\cdot)\| k_g [\langle X, \mathbf{n} \rangle \mathbf{t} - \langle X, \mathbf{t} \rangle \mathbf{n}]. \quad (2.7)$$

The Fermi-Walker derivative for our main vector fields is:

$$\begin{cases} \nabla_{\gamma}^{FW}(\gamma)(t) = \gamma'(t), & \nabla_{\gamma}^{FW}(\mathbf{t}) = 0, & \nabla_{\gamma}^{FW}(N)(t) = \|\gamma'(t)\|\tau(t)B(t), \\ \nabla_{\gamma}^{FW}(Ev(\gamma))(t) = \frac{d}{dt} \left(\frac{k_g(t)}{k(t)} \right) \gamma(t) + \|\gamma'(t)\|k(t)\langle \mathbf{n}(t), N(t) \rangle \mathbf{t}(t) + \frac{d}{dt} \left(\frac{1}{k(t)} \right) \mathbf{n}(t). \end{cases} \quad (2.8)$$

Also, the spherical Fermi-Walker derivative of our main vector fields is:

$$\begin{cases} \nabla_{\gamma}^s(\gamma)(t) = \gamma'(t), & \nabla_{\gamma}^s(\mathbf{t})(t) = -\|\gamma'(t)\|\gamma(t), & \nabla_{\gamma}^s(\mathbf{n}) = 0, \\ \nabla_{\gamma}^s(Ev(\gamma))(t) = \frac{d}{dt} \left(\frac{k_g(t)}{k(t)} \right) \gamma(t) + \|\gamma'(t)\| \frac{k_g(t)}{k(t)} \mathbf{t}(t) + \frac{d}{dt} \left(\frac{1}{k(t)} \right) \mathbf{n}(t). \end{cases} \quad (2.9)$$

3. The flow-geodesic curvature and the flow-evolute of a spherical curve

The aim of this short note is to introduce a new curvature in order to find possible new features of spherical curves; our model is the case of plane curves studied in [4]. More precisely, we first introduce a new frame along γ , denoted by \mathcal{F}^f and called the flow-spherical frame through:

$$\mathcal{F}_s^f(t) := \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos t & -\sin t \\ 0 & \sin t & \cos t \end{pmatrix} \mathcal{F}_s(t) = \begin{pmatrix} \gamma \\ E_1^f \\ E_2^f \end{pmatrix} (t) \quad (3.1)$$

and the 3×3 matrix above being an element of the subgroup $\{1\} \times SO(2)$ of the special orthonormal group $SO(3)$, we have that \mathcal{F}_s^f is also a positive oriented frame for γ . It follows that its moving equation:

$$\frac{d}{dt} \mathcal{F}_s^f(t) = \|\gamma'(t)\| \begin{pmatrix} 0 & \cos t & \sin t \\ -\cos t & 0 & k_g^f(t) \\ -\sin t & -k_g^f(t) & 0 \end{pmatrix} \mathcal{F}_s^f(t) \quad (3.2)$$

defines a new smooth function $k_g^f : I \rightarrow \mathbb{R}$ which we call the flow-geodesic curvature of γ and then if $k_g^f = 0$, we say that γ is a flow-flat spherical curve. We introduce the flow-evolute of γ as another spherical curve:

$$Ev^f(\gamma)(t) := \frac{k_g^f(t)}{\sqrt{[k_g^f(t)]^2 + 1}} \gamma(t) + \frac{1}{\sqrt{[k_g^f(t)]^2 + 1}} E_2^f(t) \in S^2. \quad (3.3)$$

We point out that \mathbf{t} , \mathbf{n} , E_1^f , and E_2^f are also spherical curves.

A straightforward computation yields:

Theorem 3.1 *The expression of the flow-geodesic curvature is:*

$$k_g^f(t) = k_g(t) - \frac{1}{\|\gamma'(t)\|} = \frac{\det(\gamma(t), \gamma'(t), \gamma''(t)) - \|\gamma'(t)\|^2}{\|\gamma'(t)\|^3} < k_g(t). \quad (3.4)$$

Therefore, γ is a flow-flat spherical curve if and only if:

$$\det(\gamma(t), \mathbf{t}(t), \gamma''(t)) = \|\gamma'(t)\|. \quad (3.5)$$

In particular, if γ is parametrized by the arc-length s and is flow-flat, then we have the conservation law: $\det(\gamma(s), \mathbf{t}(s) = \gamma'(s), \gamma''(s)) = \text{constant} = 1$.

A setting where flow-flat curves may appear interesting is as follows: fix a remarkable map $\varphi : M^n \rightarrow S^2$ from a smooth n -dimensional manifold M^n , and a smooth curve $\Gamma : I \rightarrow M$. Then we call Γ as being φ -flow-flat if its image through φ is a flow-flat spherical curve. For example, any harmonic map from a simply connected Riemann surface Σ to S^2 gives rise to a spherical surface with singularities, called spherical frontals; here spherical surface means a surface in \mathbb{R}^3 with constant and positive Gaussian curvature, see the excellent survey in [3].

Example 3.2 Another remarkable example of a map with the 2-sphere as target is the Hopf map, $H : \mathbb{C}^2 \setminus \{0\} \rightarrow S^2 \subset \mathbb{C} \times \mathbb{R}$:

$$H(u, v) = \left(\frac{2u\bar{v}}{|u|^2 + |v|^2}, \frac{|u|^2 - |v|^2}{|u|^2 + |v|^2} \right) \quad (3.6)$$

and then a curve in $\mathbb{C}^2 \setminus \{0\}$ will be Hopf-flow-flat if its image through H is a flow-flat spherical curve. \square

Following the approach of the first section, we define now a flow-spherical Fermi-Walker derivative:

$$\nabla_{\gamma}^{fs}(X) := \frac{d}{dt}X + \|\gamma'(\cdot)\|k_g^f[\langle X, \mathbf{n} \rangle \mathbf{t} - \langle X, \mathbf{t} \rangle \mathbf{n}]. \quad (3.7)$$

The flow-spherical Fermi-Walker derivative of our main vector fields is:

$$\begin{cases} \nabla_{\gamma}^{fs}(\gamma)(t) = \gamma'(t), & \nabla_{\gamma}^{fs}(\mathbf{t})(t) = -\|\gamma'(t)\|\gamma(t) + \mathbf{n}(t), & \nabla_{\gamma}^{fs}(\mathbf{n})(t) = -\mathbf{t}(t), \\ \nabla_{\gamma}^{fs}(Ev(\gamma))(t) = \frac{d}{dt} \left(\frac{k_g(t)}{k(t)} \right) \gamma(t) + \|\gamma'(t)\| \frac{k_g^f(t)}{k(t)} \mathbf{t}(t) + \frac{d}{dt} \left(\frac{1}{k(t)} \right) \mathbf{n}(t). \end{cases} \quad (3.8)$$

and then the flow-spherical Fermi-Walker derivative for the elements of the flow-spherical frame is:

$$\nabla_{\gamma}^{fs}(E_1^f)(t) = -(\|\gamma'(t)\| \cos t)\gamma(t), \quad \nabla_{\gamma}^{fs}(E_2^f)(t) = -(\|\gamma'(t)\| \sin t)\gamma(t). \quad (3.9)$$

4. Examples and remarks

In what follows we are interested in computing this new function for some remarkable spherical curves.

Example 4.1 Recall the spherical coordinates $(u, v) \in [0, 2\pi) \times [-\frac{\pi}{2}, \frac{\pi}{2}]$ giving the well-known parametrization of S^2 :

$$S^2 : \bar{r}(u, v) = (\cos u \cos v, \sin u \cos v, \sin v). \quad (4.1)$$

Fix $m \in \mathbb{R}$ and the corresponding Clelia curve [7, p. 60]:

$$\gamma_m(t) = (\cos t \cos(mt), \sin t \cos(mt), \sin(mt)) = \bar{r}(u = t, v = mt), \quad t \in \mathbb{R}. \quad (4.2)$$

Then:

$$\begin{cases} \gamma'_m(t) = (-\sin t \cos(mt) - m \cos t \sin(mt), \cos t \cos(mt) - m \sin t \sin(mt), m \cos(mt)), \\ \|\gamma'_m(t)\| = \sqrt{m^2 + \cos^2(mt)} \geq \max\{|m|, 1\} > 0 \end{cases} \quad (4.3)$$

which says that γ_m is a regular curve. It follows:

$$\begin{cases} \mathbf{n}(t) = \frac{1}{\sqrt{m^2 + \cos^2(mt)}} \left(m \sin t - \frac{1}{2} \cos t \sin(2mt), -m \cos t - \frac{1}{2} \sin t \sin(2mt), \cos^2(mt) \right), \\ k_g(t) = \frac{\sin(mt)[2m^2 + \cos^2(mt)]}{(m^2 + \cos^2(mt))^{\frac{3}{2}}} \end{cases} \quad (4.4)$$

and hence the arc $t \in (0, \frac{\pi}{m})$ is convex. The flow-geodesic curvature is:

$$k_g^f(t) = \frac{\sin(mt)[2m^2 + \cos^2(mt)]}{(m^2 + \cos^2(mt))^{\frac{3}{2}}} - \frac{1}{(m^2 + \cos^2(mt))^{\frac{1}{2}}}. \quad (4.5)$$

□

Example 4.2 A spherical curve with prescribed constant geodesic curvature $k_g = K$ and parametrized by the arc-length s is:

$$\gamma_K(s) = \frac{1}{\sqrt{1 + K^2}} \left(\cos(\sqrt{1 + K^2}s), \sin(\sqrt{1 + K^2}s), K \right) = \frac{1}{k} (\cos(ks), \sin(ks), K), s \in \mathbb{R} \quad (4.6)$$

with the spherical coordinates $(u = u(s) = ks, v = \text{constant} = \arcsin(\frac{K}{k}))$; its evolute is the constant unit vector $Ev(\gamma_K) = (0, 0, 1) = \bar{k}$ and its binormal is also constant $B = k(0, 0, 1)$. Then the flow-geodesic curvature of γ_K is the constant $k_g^f = K - 1$. It follows that γ_1 is a flow-flat convex spherical curve, $\gamma_1(s) = \frac{1}{\sqrt{2}}(\cos(\sqrt{2}s), \sin(\sqrt{2}s), 1)$, having the flow-evolute:

$$Ev^f(\gamma_1)(s) = E_2^f(s) = (\sin s) \cdot (-\sin(\sqrt{2}s), \cos(\sqrt{2}s), 0) - \frac{\cos s}{\sqrt{2}} \cdot (\cos(\sqrt{2}s), \sin(\sqrt{2}s), -1). \quad (4.7)$$

The stereographic projection from the North Pole $N(0, 0, 1)$ (respectively from the South Pole $S(0, 0, -1)$) of the parallel $\gamma_1 \in S^2$ is the plane circle centered in the origin $(0, 0)$ and having the radius $2 + \sqrt{2}$ (respectively the radius $2 - \sqrt{2}$). Concerning the example 2.2 the hypercone $H^{-1}(\gamma_1)$ of $\mathbb{C}^2 \setminus \{0\}$ is given by $|u| = (\sqrt{2} + 1)|v|$ and then any curve in this hypersurface will be a Hopf-flow-flat curve. □

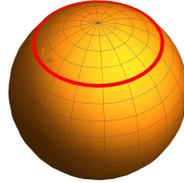

Figure 1. The flow-flat curve γ_1 of the example 4.2

Example 4.3 The tangent indicatrix of the given γ is exactly the map $t \in I \rightarrow \mathbf{t}(t) \in S^2$. Its spherical Frenet frame is:

$$\mathcal{F}_s^t := \begin{pmatrix} \mathbf{t} \\ \mathbf{t}^t \\ \mathbf{n}^t \end{pmatrix}, \mathbf{t}^t(t) := \frac{1}{k(t)} [-\gamma(t) + k_g(t)\mathbf{n}(t)], \quad \mathbf{n}^t(t) := \frac{1}{k(t)} [k_g(t)\gamma(t) + \mathbf{n}(t)]. \quad (4.8)$$

Since $\|\mathbf{t}'(t)\| = k(t)\|\gamma'(t)\|$, we get the geodesic curvature of this new spherical curve:

$$k_g^t(t) = \frac{k'_g(t)}{\|\gamma'(t)\|k^3(t)} \quad (4.9)$$

and then the flow-geodesic curvature of the tangent indicatrix is:

$$k_g^{tf}(t) = \frac{k'_g(t) - (1 + k_g^2(t))}{\|\gamma'(t)\|k^3(t)}. \quad (4.10)$$

Suppose now that γ is parametrized by arc-length. Then the tangent indicatrix is a flow-flat curve if and only if γ has the geodesic curvature $k_g(s) = \tan s$, equivalently the curvature $k(s) = \frac{-1}{\cos s}$ for $s \in (\frac{\pi}{2}, \frac{3\pi}{2})$; it follows the evolute $Ev(\gamma)(t) = -[\sin t\gamma(t) + \cos t\mathbf{tn}(t)]$. However, this curvature corresponds exactly to the expression (5) of [8, p. 363] for the constant torsion $\tau = 1$ and an explicit formula for γ involving hypergeometric functions is provided by the cited paper. The functions total curvature and total flow-geodesic curvature (on $(\frac{\pi}{2}, \frac{3\pi}{2})$) of γ are:

$$\int k(t)dt = -\ln \frac{\cos \frac{t}{2} + \sin \frac{t}{2}}{\cos \frac{t}{2} - \sin \frac{t}{2}}, \quad \int k_g(t)dt = -\ln(-\cos t). \quad (4.11)$$

□

Remark 4.4 In the paper [10], the Delaunay variational problem defined by the arc-length functional acting on the space of curves with constant torsion $\tau = 1$ is studied. A main characterization is that a biregular curve is a critical point of the Delaunay functional if and only if the associated binormal curve γ is an elastic spherical curve, i.e. there exists $\lambda \in \mathbb{R}$ such that:

$$(k_g)_{ss} + \frac{3}{2}k_g^3 + (1 - \lambda)k_g = 0. \quad (4.12)$$

Then we define the λ -elastic curvature k_e^λ of the spherical curve γ through the left-hand-side of the equation above. For our example 4.3 with $k_g(s) = \frac{\cos s}{\sin s}$, we have:

$$k_g^f(s) = \frac{\cos s}{\sin s} - 1, \quad k_e^\lambda(s) = \frac{\cos s(4 - 3\cos^2 s)}{2\sin^3 s} + (1 - \lambda)\frac{\cos s}{\sin s} \quad (4.13)$$

and then a zero of k_g^f is provided by the angle $\frac{3\pi}{4}$. □

Remark 4.5 Since we arrive at the subject of curves with constant torsion, we connect our study with the proposition 1.1 from [2, p. 216]. Fix γ a spherical curve parametrized by arc-length and a constant $\tau \neq 0$. Using the pair (γ, τ) , a new space curve is considered:

$$\Gamma(\gamma, \tau) := \frac{1}{\tau} \int \gamma \times \gamma' ds \quad (4.14)$$

and the cited theorem gives that the curvature k_Γ and torsion $\tau_\Gamma = \tau$ are related to the geodesic curvature of γ through: $k_g = k_\Gamma \cdot \tau$; then the flow-geodesic curvature of γ is $k_g^f = k_\Gamma \cdot \tau - 1$. Hence, we return to the curve γ_K of the previous example and the corresponding Γ is:

$$\Gamma_K(s) = \frac{1}{k\tau} \left(-\frac{K}{k} \sin(ks), \frac{K}{k} \cos(ks), s \right) \quad (4.15)$$

satisfying then $k_{\Gamma_K} = \frac{K}{\tau}$ and $\|\Gamma'_K(s)\| = \frac{1}{|\tau|} = \text{constant}$. Having both curvature and torsion as constants Γ_K is a helix lying on the cylinder $C : x^2 + y^2 = \frac{K^2}{k^2|\tau|}$. Its arc-length parametrization is:

$$\Gamma_K(u) = \frac{1}{k\tau} \left(-\frac{K}{k} \sin(k\tau u), \frac{K}{k} \cos(k\tau u), \tau u \right). \quad (4.16)$$

□

Example 4.6 The spherical nephroid is presented in [11, p. 353] as:

$$\gamma(t) = \left(\frac{3}{4} \cos t - \frac{1}{4} \cos 3t, \frac{3}{4} \sin t - \frac{1}{4} \sin 3t, \frac{\sqrt{3}}{2} \cos t \right). \quad (4.17)$$

Its geodesic curvature is:

$$k_g(t) = \frac{\cos t}{|\sin t|} \quad (4.18)$$

and then we restrict the parameter to $t \in (0, \pi)$; it results: $k(t) = \frac{1}{\sin t}$, $\tau = -1$. The flow-curvature of γ is:

$$k_g^f(t) = \frac{\cos t}{\sin t} - \frac{1}{\sqrt{3} \sin t} \quad (4.19)$$

and hence a zero t_0 of k_g^f is exactly *the magic angle* $t_0 = \arccos\left(\frac{1}{\sqrt{3}}\right) \simeq 0.955$. The total flow-geodesic curvature function is:

$$\int k_g^f(t) dt = \ln(\sin t) + \frac{1}{\sqrt{3}} \ln \cot \frac{t}{2}. \quad (4.20)$$
